E2-2 Microscopic Maxwell's Equation

On a scale larger than 10^{-4} Å, nuclei and electrons can be approximated as point charges, and the microscopic sources are discrete point-like moving charges in vacuum given by

$$\zeta(\mathbf{r}, t) = \sum_i q_i \delta[\mathbf{r} - \mathbf{r}_i(t)] \quad \text{Microscopic Charge Density} \quad (\text{E2.1})$$

$$\mathbf{j}(\mathbf{r}, t) = \sum_i q_i \mathbf{v}_i(t) \delta[\mathbf{r} - \mathbf{r}_i(t)] \quad \text{Microscopic Current Density}$$

velocity of point charge $\mathbf{v}_i(t)$

In the ordinary electromagnetic theory, although not essential, it is assumed that the total charge is conserved,

$$\frac{d\zeta(\mathbf{r}, t)}{dt} = 0 \quad \text{Microscopic Charge Conservation} \quad (\text{E2.2})$$

from which we can show

$$\frac{\partial \zeta(\mathbf{r}, t)}{\partial t} + \nabla \cdot \mathbf{j}(\mathbf{r}, t) = 0 \quad \text{Microscopic Current Continuity} \quad (\text{E2.3})$$

$\frac{\partial \zeta(\mathbf{r}, t)}{\partial t} + \nabla \cdot \mathbf{j}(\mathbf{r}, t) = 0$

[Q] What about the current continuity for electrons and holes in semiconductors?

In a nonrelativistic regime ($|\mathbf{v}_i| \ll c$), the dynamics of charged particles are described by the Newton-Lorentz (or simply Lorentz) force equation,

$$m_i \frac{d^2 \mathbf{r}_i(t)}{dt^2} = q_i \{ \mathbf{e}[\mathbf{r}_i(t), t] + \mathbf{v}_i(t) \times \mathbf{b}[\mathbf{r}_i(t), t] \} \quad \text{Microscopic Lorentz Force} \quad (\text{E2.4})$$

where \mathbf{e} and \mathbf{b} are the microscopic electric and magnetic fields, respectively.

Therefore, the microscopic electromagnetic phenomena, *i.e.*, the interaction between microscopic field and sources (atomic and molecular charges) is governed by the microscopic Maxwell's equations* :

$$\begin{aligned} \nabla \times \mathbf{e}(\mathbf{r}, t) &= -\frac{\partial \mathbf{b}(\mathbf{r}, t)}{\partial t} \\ \nabla \times \mathbf{b}(\mathbf{r}, t) &= \mu_0 \epsilon_0 \frac{\partial \mathbf{e}(\mathbf{r}, t)}{\partial t} + \mu_0 \mathbf{j}(\mathbf{r}, t) \\ \nabla \cdot \mathbf{e}(\mathbf{r}, t) &= \frac{1}{\epsilon_0} \zeta(\mathbf{r}, t) \\ \nabla \cdot \mathbf{b}(\mathbf{r}, t) &= 0 \end{aligned}$$

Microscopic
Maxwell's Equation (E2.5)

→ E-field, B-field

Macro-scale
= E-field, B-field

*The microscopic Maxwell's equations are important for molecular dynamics in physics and chemistry.

In contrast to the fields in macroscopic Maxwell's equations, \mathbf{e} and \mathbf{h} are the only fields defined in the microscopic Maxwell's equations.

In real materials, the atoms or molecules are spatially arranged in a certain manner, often with some defects and irregularities, and we need to consider the **free (conduction) and bound charges**, separately. The free charges can move around the lattice, while the bound charges are **immobile**, localized to the constituent atoms or molecules. Thus we can decompose the total charge and current densities into free and bound components:

$$\begin{aligned} \zeta(\mathbf{r}, t) &= \zeta_f(\mathbf{r}, t) + \zeta_b(\mathbf{r}, t) \\ \mathbf{j}(\mathbf{r}, t) &= \mathbf{j}_f(\mathbf{r}, t) + \mathbf{j}_b(\mathbf{r}, t) \end{aligned} \quad (E2.6)$$

atoms or molecules
 $\zeta(\mathbf{r}, t) = \int \rho(\mathbf{r}, t) dV$
 $\mathbf{j}(\mathbf{r}, t) = \int \mathbf{j}(\mathbf{r}, t) dV$
 $\zeta_b(\mathbf{r}, t) \sim \sum_{\alpha(n)} q_{\alpha(n)} \delta(\mathbf{r} - \mathbf{r}_{\alpha(n)}(t))$
 $\mathbf{j}_b(\mathbf{r}, t) \sim \sum_{\alpha(n)} q_{\alpha(n)} \mathbf{v}_{\alpha(n)}(t) \delta(\mathbf{r} - \mathbf{r}_{\alpha(n)}(t))$
detail expression of ζ_b and \mathbf{j}_b

where the subscripts f and b stand for “free” and “bound,” respectively,

The free and bound charges are then given by

$$\begin{aligned} \zeta_f(\mathbf{r}, t) &= \sum_{i(\text{free})} q_i \delta[\mathbf{r} - \mathbf{r}_i(t)] \quad \zeta_b(\mathbf{r}, t) = \sum_{i(\text{mol})} q_i \delta(\mathbf{r} - \mathbf{r}_i(t)) \\ \zeta_b(\mathbf{r}, t) &= \sum_{n(\text{mol})} \zeta_n(\mathbf{r}, t) \quad \zeta_b(\mathbf{r}, t) \sim \sum_{\alpha(n)} q_{\alpha(n)} \delta(\mathbf{r} - \mathbf{r}_{\alpha(n)}(t)) \end{aligned} \quad (E2.7)$$

where the bound sources (see FIG-E2.1) are then given by

$$\zeta_n(\mathbf{r}, t) = \sum_{\alpha(n)} q_{\alpha(n)} \delta[\mathbf{r} - \mathbf{r}_n(t) - \mathbf{r}_{\alpha(n)}(t)] \quad (E2.8)$$

$\sum_{\alpha(n)} q_{\alpha(n)} \delta(\mathbf{r} - \mathbf{r}_n(t) - \mathbf{r}_{\alpha(n)}(t))$

Similarly, for free and bound current densities, we have

$$\mathbf{j}_f(\mathbf{r}, t) = \sum_{i(\text{free})} q_i \mathbf{v}_i \delta[\mathbf{r} - \mathbf{r}_i(t)]$$

$$\mathbf{j}_b(\mathbf{r}, t) = \sum_{n(\text{mol})} \mathbf{j}_n(\mathbf{r}, t)$$
(E2.9)

The bound current density of the n -th molecule are then given by

$$\mathbf{j}_n(\mathbf{r}, t) = \sum_{\alpha(n)} q_{\alpha(n)} (\mathbf{v}_n + \mathbf{v}_{\alpha(n)}) \delta[\mathbf{r} - \mathbf{r}_n(t) - \mathbf{r}_{\alpha(n)}(t)]$$
(E2.10)

where we use local coordinates for molecule as shown in FIG-E2.1:

$\mathbf{r}_n(t), \mathbf{v}_n(t)$: position, velocity of the n -th molecule
 $q_{\alpha(n)}, \mathbf{r}_{\alpha(n)}(t), \mathbf{v}_{\alpha(n)}(t)$: charge, position, velocity of the α -th charge within the n -th molecule (local coordinate)

Note that the local (inside the molecule) and laboratory (observation) coordinates have very different scales:

$$|\mathbf{r}_{\alpha(n)}| \ll |\mathbf{r}_n| \ll |\mathbf{r}|$$

inside molecule (pointing to $|\mathbf{r}_{\alpha(n)}|$)
molecular position (pointing to $|\mathbf{r}_n|$)

definition of lse (pointing to the equation)
 ⇒ different.

(E2.11)

[Q] What about the current continuity for electrons and holes in semiconductors?

$N_A \rightarrow N_D$

FIG-E2.1 Coordinates for bound charges in a molecular system

E2-2 Macroscopic Maxwell's Equation: Simple Spatial Average

The number of electrons and nuclei in a macroscopic amount of a material are of the order of 10^{23} . Even in the absence of external fields, there will exist **microscopic fields** due to the thermal agitation, orbital motion, and even zero-point vibration of the charged particles.

These microscopic fields usually vary extremely rapidly in both space and time. The spatial variation occurs in a distance shorter than 0.01 \AA , and the period of the temporal fluctuation is in the range of $0.01 \text{ fs} \sim 0.1 \text{ ps}$. *→ fast process.*

Consequently, for any macroscopic measurement in the real world, where the spatial averaging process inevitably occurs. This means that we need more practical governing equations than the microscopic Maxwell's equations.

c.f. convolution.

Spatial Average

The spatial average of a function $f(\mathbf{r}, t)$ by a macroscopic measurement can be described by using a sampling function $F_s(\mathbf{r}, t)$.

$$\langle f(\mathbf{r}, t) \rangle = \int d^3\mathbf{r}' f(\mathbf{r}, t) F_s(\mathbf{r} - \mathbf{r}') \quad (\text{E2.12})$$

moving area.

[Q] How about $\langle f(\mathbf{r}, t) \rangle = \int d^3\mathbf{r}' f(\mathbf{r}, t) F_s(\mathbf{r} - \mathbf{r}') ?$

Sampling function $\propto \delta^3(\mathbf{r})$

The properties of $F_s(\mathbf{r}, t)$ do not need to be specified in all the detail, except that it is just a “well behaved” function that is localized to a molecular dimension, with a normalization condition:

$$\int d^3\mathbf{r}' F_s(\mathbf{r}') = 1 \quad (\text{E2.13})$$

After averaging (E2.5), we have the macroscopic Maxwell's equations:

$$\begin{aligned} \nabla \times \mathbf{E}(\mathbf{r}, t) &= -\frac{\partial \mathbf{B}(\mathbf{r}, t)}{\partial t} \\ \nabla \times \mathbf{B}(\mathbf{r}, t) &= \mu_0 \epsilon_0 \frac{\partial \mathbf{E}(\mathbf{r}, t)}{\partial t} + \mu_0 \mathbf{J}(\mathbf{r}, t) \end{aligned} \quad (\text{E2.14})$$

$$\nabla \cdot \mathbf{E}(\mathbf{r}, t) = \frac{1}{\epsilon_0} \rho(\mathbf{r}, t)$$

$$\nabla \cdot \mathbf{B}(\mathbf{r}, t) = 0$$

Here, we define the macroscopic fields and sources as

$$\begin{aligned} \mathbf{E}(\mathbf{r}, t) &= \langle \mathbf{e}(\mathbf{r}, t) \rangle, & \mathbf{B}(\mathbf{r}, t) &= \langle \mathbf{b}(\mathbf{r}, t) \rangle \\ \rho(\mathbf{r}, t) &= \langle \zeta(\mathbf{r}, t) \rangle, & \mathbf{J}(\mathbf{r}, t) &= \langle \mathbf{j}(\mathbf{r}, t) \rangle \end{aligned} \quad (\text{E2.15})$$

Note that we still have only the macroscopic fields, $\mathbf{E}(\mathbf{r}, t)$ and $\mathbf{B}(\mathbf{r}, t)$.
